Vision of the Department

To educate students with conceptual knowledge and technical skills in the field of Information Technology with moral and ethical values to achieve excellence in an academic, industry and research centric environment.

Mission of the Department

1. To inculcate in students a firm foundation in theory and practice of IT skills coupled with the thought process for disruptive innovation and research methodologies, to keep pace with emerging technologies.
2. To provide a conducive environment for all academic, administrative, and interdisciplinary research activities using state-of-the-art technologies.
3. To stimulate the growth of graduates and doctorates, who will enter the workforce as productive IT engineers, researchers, and entrepreneurs with necessary soft skills, and continue higher professional education with competence in the global market.
4. To enable seamless collaboration with the IT industry and Government for consultancy and sponsored research.
5. To cater to cross-cultural, multinational, and demographic diversity of students.
6. To educate the students on the social, ethical, and moral values needed to make significant contributions to society.
Program Educational Objectives (PEO)

After completion of the B.Tech. (IT) course, students will be able to:

**PEO1:** Demonstrate core competence in basic engineering and mathematics to design, formulate, analyse, and solve hardware/ software engineering problems.

**PEO2:** Have insight in fundamental areas of Information Technology and related engineering with an inclination towards self-learning to address real-world problems using digital and cognitive technologies.

**PEO3:** Collaborate with industry, academic and research institutions for product and research related development.

**PEO4:** Imbibe high professionalism, effective communication skills and team spirit to work on multidisciplinary projects, in diverse professional environments.

**PEO5:** Practice IT solutions following technical standards with ethical values.

Program Specific Outcomes (PSO)

**PSO1:** To apply programming principles and practices for the design of software solutions in an internet-enabled world of business and social activities.

**PSO2:** To identify the resources to build and manage the IT infrastructure using the current technologies in order to solve real world problems with an understanding of the trade-offs involved in the design choices.

**PSO3:** To plan, design and execute projects for the development of intelligent systems with a focus on the future.
OBJECTIVES:
- To learn about the basic commands of operating systems
- To learn various process management schemes in operating systems
- To practice with the important memory management mechanisms in operating system
- To implement the file handling techniques in operating systems

Exercises
1. Basic unix commands such as ls, cd, mkdir, rmdir, cp, rm, mv, more, lpr, man, grep, sed, etc.,
2. Shell script
3. Process control System calls - demonstration of fork, execute and wait
4. Thread management
5. Thread synchronization
6. Deadlock avoidance using semaphores
7. Interprocess communication using pipes
8. Interprocess communication using FIFOs
9. Interprocess communication using signals
10. Implementation of CPU scheduling policy in Linux
11. Implement a memory management policy in Linux
12. Implement a file system in Linux
13. Linux kernel configuration

OUTCOMES:
On Completion of the course, the students should be able to:
- Learn the concepts to identify, create and maintain the basic command in operating systems
- Express strengths and limitations of various managements schemes in operating systems
- Explain the core issues of operating systems
- Implement algorithms of operating systems.
## Mapping of Course Outcomes (COs) with Program Outcomes (POs)

<table>

EX.NO: 1 INTRODUCTION TO OPERATING SYSTEMS

AIM

To the study the functions of an operating system.

1.1 OVERVIEW

An Operating System (OS) (as shown in Fig 1) is an interface between a computer user and computer hardware. An operating system is a software which performs all the basic tasks like file management, memory management, process management, handling input and output, and controlling peripheral devices such as disk drives and printers.

Some popular Operating Systems include Linux Operating System, Windows Operating System, VMS, OS/400, AIX, z/OS, etc. Following are some of important functions of an operating System:

- Memory Management
- Processor Management
- Device Management
- File Management
- Security
- Control over system performance
- Job accounting
- Error detecting aids
- Coordination between other software and end users.

Figure 1. Operating System
1.2 LINUX OPERATING SYSTEM

Linux is a free and open source operating system and it is a clone version of UNIX operating system. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

1.2.1 LINUX ARCHITECTURE

Figure 2. Linux OS Architecture

The architecture of a linux system consists of the following layers –

**Hardware layer**

Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc).

**Kernel**

It is the core component of Operating System, interacts directly with hardware, provides low level services to upper layer components.
Shell

An interface to kernel, hiding complexity of kernel's functions from users. The shell takes commands from the user and executes kernel's functions.

Utilities

Utility programs that provide the user most of the functionalities of an operating systems.

1.2.2 COMPONENTS OF A LINUX OPERATING SYSTEM

Linux operating system has primarily three components:

Kernel

Kernel is the core part of linux. It is responsible for all major activities of this operating system. It consists of various modules and it interacts directly with the underlying hardware. Kernel provides the required abstraction to hide low level hardware details to system or application programs.

System Library

System libraries are special functions or programs using which application programs or system utilities accesses Kernel's features. These libraries implement most of the functionalities of the operating system and do not requires kernel module's code access rights.

System Utility

System Utility programs are responsible to do specialized, individual level tasks.

Figure 3. Linux Operating System
1.2.3 KERNEL MODE VS USER MODE

Kernel component code executes in a special privileged mode called kernel mode with full access to all resources of the computer. This code represents a single process, executes in single address space and do not require any context switch and hence is very efficient and fast. Kernel runs each processes and provides system services to processes, provides protected access to hardware to processes.

Support code which is not required to run in kernel mode is in System Library. User programs and other system programs works in User Mode which has no access to system hardware and kernel code. User programs/ utilities use System libraries to access Kernel functions to get system’s low level tasks.

1.2.4 BASIC FEATURES

Following are some of the important features of linux operating system

- **Portable**

  Portability means software can work on different types of hardware in same way. Linux kernel and application programs supports their installation on any kind of hardware platform.

- **Open Source**

  Linux source code is freely available and it is community based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.

- **Multi User**

  Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.

- **Multiprogramming**

  Linux is a multiprogramming system means multiple applications can run at same time.

- **Hierarchical File System**

  Linux provides a standard file structure in which system files/ user files are arranged.
• **Shell**
  Linux provides a special interpreter program which can be used to execute commands of the operating system. It can be used to do various types of operations, call application programs, etc.

• **Security**
  Linux provides user security using authentication features like password protection/controlled access to specific files/encryption of data.

**1.3 COMPARISONS BETWEEN LINUX OS WITH DIFFERENT OS**

**1.3.1 LINUX VS WINDOWS**

**Linux OS**

Linux could be a free and open supply OS supported operating system standards. It provides programming interface still as programme compatible with operating system primarily based systems and provides giant selection of applications. A UNIX operating system additionally contains several severally developed parts, leading to UNIX operating system that is totally compatible and free from proprietary.

**Windows OS**

Windows may be a commissioned OS within which ASCII text file is inaccessible. it's designed for the people with the angle of getting no programming information and for business and alternative industrial users. it's terribly straightforward and simple to use.

The distinction between Linux and Windows package is that Linux is completely freed from price whereas windows is marketable package and is expensive. Associate operating system could be a program meant to regulate the pc or computer hardware.

Linux is an open supply package wherever users will access the ASCII text file and might improve the code victimisation the system. On the opposite hand, in windows, users can’t access ASCII text file, and it’s an authorized OS.

Let’s see that the difference between Linux and windows:
<table>
<thead>
<tr>
<th>S.N</th>
<th>LINUX</th>
<th>WINDOWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>It is an open source operating system</td>
<td>It is a commercial operating system (closed source)</td>
</tr>
<tr>
<td>2.</td>
<td>In linux, monolithic kernel is used</td>
<td>In windows, micro kernel is used.</td>
</tr>
<tr>
<td>3.</td>
<td>In the comparison of file system, linux runs faster even with older hardware</td>
<td>Windows are slower compared to Linux</td>
</tr>
<tr>
<td>4.</td>
<td>Linux files are ordered in a tree structure starting with the root directory.</td>
<td>In windows, files are stored in folders on different data drives like C: D: E:</td>
</tr>
<tr>
<td>5.</td>
<td>It is customizable</td>
<td>It is not possible to customize the windows OS</td>
</tr>
<tr>
<td>6.</td>
<td>It supports multiple desktop environments</td>
<td>It supports only preinstalled desktop environment</td>
</tr>
<tr>
<td>7.</td>
<td>It is more secure than windows</td>
<td>Vulnerable to viruses and malware attacks.</td>
</tr>
<tr>
<td>8.</td>
<td>Booting takes either primary or logical partition in linux</td>
<td>In windows, booting supports only primary partition</td>
</tr>
</tbody>
</table>

### 1.3.2 LINUX VS MAC

**Linux**

Linux is a group of open source Unix-like operating systems which was developed by Linus Torvalds. It is a packaged of Linux distribution. Some of the mostly used Linux distribution are Debian, Fedora and Ubuntu. It was basically written in C language and assembly language. Kernel used in Linux is Monolithic kernel. The target systems of Linux distributions are cloud computing, embedded systems, mobile devices, personal computers, servers, mainframe computers and supercomputers. The first version of Linux was launched in 1991.

**MAC**

Mac OS is a series of proprietary graphical operating systems which is provided by Apple Incorporation. It was earlier known as Mac OS X and later OS X. It is specifically designed for Apple mac computers. It is based on Unix operating system. It was developed using C, C++, Objective-C, assembly language and Swift. It is the second most used operating system in personal computers after Windows. The first version of macOS was launched by Apple in 2001.
Let’s sees that the difference between Linux and mac:

<table>
<thead>
<tr>
<th>S.N</th>
<th>LINUX</th>
<th>MAC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>It is an open source operating system</td>
<td>It is a commercial operating system (closed source)</td>
</tr>
<tr>
<td>2.</td>
<td>In linux, monolithic kernel is used</td>
<td>MacOS is based the Xnu hybrid micro kernel</td>
</tr>
<tr>
<td>3.</td>
<td>It is used as OS, as server provide</td>
<td>Mac is an operating system provides platform to run other application</td>
</tr>
<tr>
<td></td>
<td>platform to run other application</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>It is customizable</td>
<td>It is not possible to customize the Mac OS</td>
</tr>
<tr>
<td>5.</td>
<td>It supports many flavours like RedHat,</td>
<td>It does have any flavours.</td>
</tr>
<tr>
<td></td>
<td>Ubuntu, Fedora, Suse, etc,</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>It supports multiple desktop environments</td>
<td>It supports only preinstalled desktop</td>
</tr>
<tr>
<td></td>
<td>like GNOME, KDE, Mate, Budgie, Cinnamon,</td>
<td>environment</td>
</tr>
<tr>
<td></td>
<td>Deepin etc,…</td>
<td></td>
</tr>
</tbody>
</table>

1.3.3 LINUX VS UNIX

Linux

Linux is an open source multi-tasking, multi-user operating system. It was initially developed by Linus Torvalds in 1991. Linux OS is widely used in desktops, mobiles, mainframes etc.

Unix

Unix is multi-tasking, multi-user operating system but is not free to use and is not open source. It was developed in 1969 by Ken Thompson team at AT&T Bell Labs. It is widely used on servers, workstations etc. Following are the important differences between Linux and Unix.

Let’s sees that the difference between Linux and windows:
<table>
<thead>
<tr>
<th>S.N</th>
<th>LINUX</th>
<th>UNIX</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>It is an open source operating system</td>
<td>It is a licensed OS (closed source)</td>
</tr>
<tr>
<td>2.</td>
<td>It is developed by linux community of developers</td>
<td>It was developed by AT and T Bell labs</td>
</tr>
<tr>
<td>3.</td>
<td>Linux uses KDE and Gnome. Other GUI supported are LXDE, Xfce, Unity, Mate.</td>
<td>Unix was initially a command based OS. Most of the unix distributions now have Gnome.</td>
</tr>
<tr>
<td>4.</td>
<td>Bash (Bourne Again SHell) is default shell for Linux.</td>
<td>Bourne Shell is default shell for Unix.</td>
</tr>
<tr>
<td>5.</td>
<td>Its flavours are RedHat, Ubuntu, Suse, Kali Linux, etc,…</td>
<td>Its flavours are SunOS, Solaris, HP-UX, AIX, Sco Unix, etc,…</td>
</tr>
<tr>
<td>6.</td>
<td>Linux is used in wide varieties from desktop, servers, smartphones to mainframes.</td>
<td>It is mostly used on servers, workstations or PCs.</td>
</tr>
</tbody>
</table>

1.4 SCHEDULING OF JOBS IN OPERATING SYSTEM

Job scheduling is the process of allocating system resources to many different tasks by an operating system (OS). The system handles prioritized job queues that are awaiting CPU time and it should determine which job to be taken from which queue and the amount of time to be allocated for the job.

This type of scheduling makes sure that all jobs are carried out fairly and on time. Most OSs like Unix, Windows, etc., include standard job-scheduling abilities. A number of programs including database management systems (DBMS), backup, enterprise resource planning (ERP) and business process management (BPM) feature specific job scheduling capabilities as well.

1.5 PROCESS MANAGEMENT

Process management involves various tasks like creation, scheduling, termination of processes, and a dead lock. Process is a program that is under execution, which is an important part of modern-day operating systems. The OS must allocate resources that enable processes to share and exchange information.

It also protects the resources of each process from other methods and allows synchronization among processes. It is the job of OS to manage all the running processes of the system. It handles operations by performing tasks like process scheduling and such as resource allocation.
1.6 PROCESS ARCHITECTURE

Stack

The stack stores temporary data like function parameters, returns addresses, and local variables.

Heap

It allocates memory, which may be processed during its run time.

Data

It contains the variable.

Text

It includes the current activity, which is represented by the value of the Program Counter.

1.7 MEMORY MANAGEMENT IN OPERATING SYSTEMS

Memory management is the functionality of an operating system which handles or manages primary memory and moves processes back and forth between main memory and disk during execution. Memory management keeps track of each and every memory location, regardless of either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.

The operating system takes care of mapping the logical addresses to physical addresses at the time of memory allocation to the program. There are three types of addresses used in a program before and after memory is allocated –

1. Symbolic addresses

The addresses used in a source code. The variable names, constants, and instruction labels are the basic elements of the symbolic address space.

2. Relative addresses

At the time of compilation, a compiler converts symbolic addresses into relative addresses.

3. Physical addresses

The loader generates these addresses at the time when a program is loaded into main memory.
1.8 SYSTEM CALLS IN OPERATING SYSTEMS

System call is a mechanism that provides the interface between a process and the operating system. It is a programmatic method in which a computer program requests a service from the kernel of the OS. System call offers the services of the operating system to the user programs via API (Application Programming Interface). System calls are the only entry points for the kernel system. For example, if we need to write a program code to read data from one file, copy that data into another file.

The first information that the program requires is the name of the two files, the input and output files. In an interactive system, this type of program execution requires some system calls by OS.

- First call is to write a prompting message on the screen.
- Second, to read from the keyboard, the characters which define the two files.

1.9 DAY TO DAY USAGE OF OPERATING SYSTEMS

The operating system is used everywhere nowadays especially such as banks, schools, colleges, universities, govt. organizations, IT companies, mobile, etc, ...

No device can operate without an operating system because it controls all the user’s commands. Linux /unix operating systems is used in bank because it’s very secure operating systems.

Symbian OS, windows mobile, IOS and Android OS are used in mobile phones operating systems as these operating systems are a lightweight operating systems.

RESULT

The architecture and features of an operating system has been studied successfully.
EX.NO: 2 LINUX COMMANDS FILE SYSTEM

AIM
To study and implement about the various basic linux commands.

I. FILE RELATED COMMANDS

1. cat

- The cat command is used to create a file.
- The cat command is used to display the contents of a file.
- The cat command is also used merge multiple files into a single file

Syntax

1.1 File Creation & Display its Contents using cat command

```
$ cat > filename  (Create a new file)
$ cat <filename>  (Display the contents of file)
$ cat file1 file2 >file3  (merge the contents of file1, file2 into file 3)
```
1. 2 Files Merging using cat command

```
sh-4.3$ cat >au.txt
India is a my country
sh-4.3$ cat >ind.txt
MIT is a green campus of AU.
India is a my country
sh-4.3$ cat mit.txt ind.txt >test.txt
sh-4.3$ cat test.txt
```

2. ls command

- Listing files and directories
- The ls command is used to display the contents of a directory.

**Syntax**

```
$ ls  → View the contents of directory
```

2. Displaying Files and Folders

```
sh-4.3$ ls
README.txt au.txt ind.txt krish mit.txt pugazh ram test.txt vpm
sh-4.3$
```
3. clear command
   - This command is used to clear the terminal screen
   - $ clear

II. DIRECTORY RELATED COMMANDS
1. mkdir
   - This command is used create an **empty directory in a disk**

Syntax
   $ mkdir <dname>

1.1 Empty Directory Creation

2. rmdir
   - This command is used remove a **directory from the disk**

Rules for Directory Deletion
   - Directory must be empty
   - Directory can't be current working directory

Syntax
   $ rmdir <dname>
2.1 Empty Directory Deletion

3. cd
   - This command is used to move from one directory to another directory.

**Syntax**

\$ cd <dname>

3.1 Changing the Working Directory
4. pwd

- pwd stands for "print working directory"
- This command is used to print the current working directory

**Syntax**

$ cd <dname>

4.1 Displaying Current Working Directory

III. General Purpose Commands

1. date command

- This command is used to display the current date with day, month, date, time (24 Hrs clock) & year
- $ date

1. Output
2. **cal** command

- Linux calendar
- This command is used to display the current month, all months of particular year
- `$ cal` (Show the current month of current year)
- `$ cal 2015` (Show all months in year 2015)

### 2.1 Displaying Current Month

![Terminal output showing the current month of July 2015](image-url)
2.2 Displaying Entire Year

3. tty command

- The tty (teletype) command is used to print the current terminal name
- `$ tty`
3.1 Displaying Terminal Name

RESULT

Thus the linux commands have been studied and executed successfully.
EX.NO: 3 SHELL PROGRAMMING BASICS

AIM
To execute the fundamentals of shell programming such as control flow statements.

EXISTING PROBLEM
- It is not possible to perform more than one task at a time using shell command

SHELL SCRIPTS (MULTITASKING)
- In order to solve the problems of shell command, the shell programming is introduced here
- Doing more than one job at a time (multitasking)
- It is also called as shell programming

VARIABLES SECTION
- Names given to the memory location
- Shell program supports dynamic data typed system which means that no need to use specific data type for variables declaration

Syntax

```
Variable-Name=Initial-Value
```

Example

```
a=10  # integer type
str="Sachin"  # string type
c='G'  # character type
f=true  # boolean value
readonly id=14  # integer constant
```
I. EXAMPLE OF DATA TYPES IN SHELL CODE

SOURCE CODE

echo "------------------------------------"
echo "\tShell Data Types"
echo "------------------------------------"

# variables definition
a=19
b=15.45
c='S'
str="Sachin"
flag=true

# constant variable definition
readonly id=99

echo "Int\t\t\t\t\t-> $a"
echo "Float\t\t\t\t-> $b"
echo "Character\t\t\t-> $c"
echo "Name\t\t\t\t-> $str"
echo "Boolean\t\t\t-> $flag"

echo "Int Constant\t\t-> $id"

2. OUTPUT

"sh datatype.sh"

\n
<table>
<thead>
<tr>
<th>Shell Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int</td>
</tr>
<tr>
<td>Float</td>
</tr>
<tr>
<td>Character</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
<tr>
<td>Int Constant</td>
</tr>
</tbody>
</table>

"."
COMMENT LINE STATEMENTS

- Usually these statements are ignored by compiler or interpreter
- Like c/c++, shell supports two types of comment line statements. They are
  1. Single line statement
  2. Multi line statements

1. Single line statement
   - The single line statement is indicated by `# symbol` in shell program

Example

```
# This is single line statement
```

2. Multi line statements
   - It is used to ignore more than one statements
   - This is indicated by `:' ' symbol in shell program

Example

```
:' Variable Declarations
   a=20
   k=25
:'
```

SELECTION STATEMENTS

1. Simple If statement
2. If else Statement
3. If else if Statement
4. Case Statement
1. Simple If Statement

**Syntax**

```plaintext
if [ condition ]
then
    true statement
fi
```

- It is important to note that, the space should be given before and after the operator symbol `[`.
- You can use `test` keyword instead of the operator symbols `[ ]`.

2. If else Statement

**Syntax**

```plaintext
if [ condition ]
then
    true statement
else
    false statement
fi
```
3. If…elif…else Statement

Syntax

```bash
if [ condition ]
then
  true statement
elif [ condition ]
then
  true statement
else
  false statement
fi
```

- It is an important to note that, the simple if, if else and if-elif-else should be closed by `fi` keyword.

4. Case Statement

- It is equivalent to switch case statements in c language
- It is used to execute several statements based on the value of expression
- This is done by using the reserved word `case`
- It is an alternative option for if..elif..else statements

Syntax

```bash
case <variable> in
  Pattern 1)
    Commands / statements
    ;;
  Pattern 2)
    Commands / statements
    ;;
  ...
easc
```
Where,

```
;; → represents the break part in case statements
```

LOOPING STATEMENTS

1. While loop  (while)
2. Until loop    (until)
3. For loop     (for)

1. While loop

Syntax

```
while [ condition ]
do
  true statement
done
```

Infinite While loop

- It is an important to note that, the colon (:) operator or true keyword is used for creating an infinite loop
- The colon (:) operator is used instead of the operator symbols [ ]

II. EXAMPLE OF INFINITE LOOP USING WHILE LOOP

SOURCE CODE

```
while :
do  
echo "Hello World"
done

(OR)

while true
do  
echo "Hello World"
```
**OUTPUT**

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello World</td>
<td></td>
</tr>
<tr>
<td>Hello World</td>
<td></td>
</tr>
<tr>
<td>Hello World</td>
<td></td>
</tr>
<tr>

</tbody>
</table>
2. Until loop

- Here loop is executing until the condition is false
- If the condition becomes true it will exit from the loop

Syntax

```
until [ condition ]
do
  true statement
done
```

III. EXAMPLE OF UNTIL LOOP

**SOURCE CODE**

```
echo "-----------------------------------------------"
echo "\nUntil Loop Example"
ext "-----------------------------------------------"
i=1
until [ $i -gt 5 ]
do
  echo $i
  i=`expr $i + 1`
done
```

Here the looping statements are executed until the condition becomes fail like 1>5, 2>5, 3>5, 4>5, 5>5

This loop will terminate whenever the condition becomes true like 6>5
OUTPUT

![Console output](image)

3. For loop

Syntax

```plaintext
for variable in w1 w2 ... wn
do
    true statement
done
```

Where,

Variable can be any user defined name

w1 w2 ... wn → list of the values separated by spaces
IV. EXAMPLE OF FOR LOOP

SOURCE CODE

```bash
echo "-------------------------------------"
echo "\t For Loop Example"
echo "-------------------------------------"
for i in 12 14 15 17 18 21
doi
    echo $i
done
```

OUTPUT

![Console Output]

V. CHARACTERS AND STRING RETRIEVAL USING FOR LOOP

SOURCE CODE

```bash
echo "-------------------------------------"
echo "\t Char & String Retrieval using for loop"
echo "-------------------------------------"
for i in 'Sachin' 'B' "C" "D" 'E'
doi
    echo $i
done
```
VI. DISPLAYING FILES AND DIRECTORIES USING FOR LOOP

**SOURCE CODE**

```bash
# Store list of files to the variable fset using ls command.
# get all the files and store them to variable
fset=`ls`
k=1
# loop the variable fset
for i in $fset
do
    echo "$k. $i"
    k=`expr $k + 1`
done
```

**Command Substitution:**
Storing the output of command to a user defined variable. This is done by using the operator `command` or `$(command)`
VII. FACTORIAL OF A NUMBER

Language : shell (.sh)
Editor : replit.com (Online Linux Terminal)
OS : Windows 10

SOURCE CODE

```bash
echo "--------------------------------------"
echo "\tFactorial Program"
echo "--------------------------------------"
echo "Enter a number : "
read n
i=0
f=1
while [ $i -lt $n ]
```
do
# increment i by 1
i=`expr $i + 1`
f=`expr $f \* $i`
done
echo "The Factorial of $n is : $f"

OUTPUT

```
> sh fact.sh

Factorial Program
Enter a number :
5
The Factorial of 5 is : 120
> sh fact.sh

Factorial Program
Enter a number :
6
The Factorial of 6 is : 720
> 
```

C STYLE CODING IN SHELL

- In shell, we can use c style coding for looping statements and expressions
- The expressions are defined by $(exp)$. Here each is also closed by () symbol.
VIII. FACTORIAL OF A NUMBER USING C-STYLE

SOURCE CODE

```bash
echo "---------------------------------------------"
echo "\tFactorial Program- C Style"
echo "---------------------------------------------"
echo "Enter a number : 
read n
i=1
f=1
# while loop
while [ $i -le $n ]
do
# expression 1 in c-style
  f=($f*i)
# expression 2 in c-style
  i=($i+1)
done
echo "Factorial of $n is $f"
```

OUTPUT

```bash
$ sh fact1.sh
---------------------------------------------
Factorial Program- C Style
---------------------------------------------
Enter a number :
5
Factorial of 5 is 120
$ sh fact1.sh
---------------------------------------------
Factorial Program- C Style
---------------------------------------------
Enter a number :
6
Factorial of 6 is 720
```

$
IX. REVERSE OF A NUMBER

SOURCE CODE

echo "--------------------------------------------"  
echo "\t\tReverse of Number"  
echo "--------------------------------------------"  
echo "Enter a number : "  
read n  
duplicate=$n  
res=0  
while [ $n -ne 0 ] do  
  # find the reminder  
  rem=`expr $n % 10`  
  # multiply reverse number with 10  
  res=`expr $res \* 10`  
  # add the resultant number with remainder number  
  res=`expr $res + $rem`  
  # divide n by 10  
  n=`expr $n / 10`  
done  
echo "The Reverse Number of $duplicate is $res"
X. ARMSTRONG NUMBER

SOURCE CODE

```bash
echo "--------------------------------------------"  
echo "\t\tArmstrong Number"  
echo "--------------------------------------------"  
echo "enter a number"  
read n  
# variables declarations  
dup=$n  
arm=0  
# while loop  
while test $n -ne 0 do  
  # find remainder of a number  
  rem=`expr $n % 10`  
  # multiply rem with three times  
  rem=`expr $rem \* $rem \* $rem`  
  # add the resultant remainder with arm variable  
  arm=`expr $arm + $rem`  
  dup=`expr $dup - $n`  
  n=`expr $n / 10`  
while (n!=0)
  rem=n%10
  rem=(rem*rem*rem)
done  
```

```

Enter a number : 6724
The Reverse Number of 6724 is 4276

Enter a number : 45
The Reverse Number of 45 is 54

Enter a number : 12662
The Reverse Number of 12662 is 26621

```

IT7411 – OS LABORATORY (4/8 B.TECH – IT) 41|Page
```bash
arm=`expr $arm + $rem`
# divide n by 10
n=`expr $n / 10`
done
if [ $dup -eq $arm ]
then
  echo "Given Number $dup is Armstrong Number"
else
  echo "Given Number $dup is not Armstrong Number"
fi
```

**OUTPUT**

```
> ah armstrong.sh
-------------------------------------
Armstrong Number
-------------------------------------
Enter a number
153
Given Number 153 is Armstrong Number
> ah armstrong.sh
-------------------------------------
Armstrong Number
-------------------------------------
Enter a number
283
Given Number 283 is not Armstrong Number
```

**XI. MENU DRIVEN PROGRAM**

**SOURCE CODE**

```
while [ true ]
do
echo "-------------------------------------"
echo "\t\t Menu Program"
echo "-------------------------------------"
echo "1. View Files \t 2. Date"
echo "3. Users List \t 4. Calendar"
echo "5. Exit"
```
echo "Enter ur choice : "
read ch
# switch case
 case $ch in
   1) ls;;
   2) date;;
   3) w;;
   4) cal;;
   5) exit;;
 esac
# read choice from user for continuation of program execution
echo "Do you want to continue : Press Yes/No"
read ch
if [ $ch = "yes" ] || [ $ch = "Yes" ] || [ $ch = "YES" ]
then
   continue
else
   exit
fi
done

NOTE

- It is an important to note that, the single equal operator (=) is used for string comparison and the symbol -eq or == is used for number comparison in the shell program.
OUTPUT

```
> sh menup.sh

Menu Program

1. View Files  2. Date

Enter your choice:

**COMMAND LINE ARGUMENTS (POSITIONAL PARAMETERS)**

- Process of passing the input arguments to the program at the time of execution is called as command line arguments
- In shell, this is done with help of $ symbol

<table>
<thead>
<tr>
<th>S.N</th>
<th>POSITIONAL PARAMETERS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>$0</td>
<td>Indicates the filename itself</td>
</tr>
<tr>
<td>2.</td>
<td>$1</td>
<td>Indicates the first argument</td>
</tr>
<tr>
<td>3.</td>
<td>$2</td>
<td>Indicates the second argument</td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>$*</td>
<td>Represents the total number of input arguments which are submitted to the shell program</td>
</tr>
<tr>
<td>5.</td>
<td>$#</td>
<td>Shows the count of total number of arguments passed to the shell program</td>
</tr>
</tbody>
</table>
I. EXAMPLE OF COMMAND LINE INPUTS

SOURCE CODE

```bash
echo "----------------------------------------------"
echo "\t\tCommand Line Arguments (Input)"
echo "----------------------------------------------"
a=$1
b=$2
# check whether the command line arguments are submitted or not
if [ $# -ne 0 ]
then
    r=`expr $a + $b`
    echo "Sum is: $r"
else
    echo "No inputs are submitted...Please submit the CMD inputs..."
fi
```

OUTPUT

```
\$ sh cmd.sh 4 5
----------------------------------------------
Command Line Arguments (Input)
----------------------------------------------
Sum is: 9
\$ sh cmd.sh
----------------------------------------------
Command Line Arguments (Input)
----------------------------------------------
No inputs are submitted...Please submit the CMD inputs...
```

II. EXAMPLE OF COMMAND LINE INPUTS – MUCH ARGUMENTS

SOURCE CODE

```
echo "--------------------------------------------------"
echo "\t\t\tCommand Line Arguments"
echo "--------------------------------------------------"
# check whether the command line arguments are submitted or not
if [ $# -ne 0 ]
then
    echo "Total Input Arguments are Submitted: $#"
    for i in $*
    do
        echo $i
    done
else
    echo "No inputs are submitted...Please submit the CMD inputs..."
fi
```

OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; sh cmd1.sh 45 12 21 Shiva true 191</td>
<td>![Command Line Output]</td>
</tr>
</tbody>
</table>

```
Command Line Arguments
Total Input Arguments are Submitted: 6
45
12
21
Shiva
ture
191
```

RESULT

Thus the basics of shell programming was executed successfully.
EX.NO: 4  SHELL SCRIPTING – OPERATORS, FUNCTIONS

AIM
To practice the different types of operators using shell programming

OPERATORS
- A special symbol which is used to perform the various tasks such as arithmetic operations, relational operations, logical operations, file testing operations, comparisons, etc, ...

ARITHMETIC OPERATORS

<table>
<thead>
<tr>
<th>S.N</th>
<th>OPERATOR</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>+</td>
<td>Addition</td>
</tr>
<tr>
<td>2.</td>
<td>-</td>
<td>Subtraction</td>
</tr>
<tr>
<td>3.</td>
<td>*</td>
<td>Multiplication</td>
</tr>
<tr>
<td>4.</td>
<td>/</td>
<td>Division</td>
</tr>
</tbody>
</table>

EXPRESSION IN SHELLS
- Shell provides two options for performing expressions in shell scripts. They are

  1. Using expr command → Shell style expr
  2. Using double braces () → C Style $(exp)

NOTE
- It is an important to note that, the operator * does not provide the multiplication in shell expression using expr command. Because in shell, the operator * means wild card characters.
- So, the backward slash followed by * symbol \* is to provide the multiplication expression in shell expression using expr command.
I. EXAMPLE OF ARITHMETIC OPERATIONS USING EXPR COMMAND

SOURCE CODE

```bash
echo "-----------------------------------------------"  
echo "\tArithmetic Operations using expr command"  
echo "-----------------------------------------------"  
echo "Enter the number 1: "  
read a  
echo "Enter the number 2: "  
read b  
# performing arithmetic operations using expr command  
r1=`expr $a + $b`  
r2=`expr $a - $b`  
r3=`expr $a \* $b`  
r4=`expr $a / $b`  
# print the results  
echo "Add: \t$r1"  
echo "Sub: \t$r2"  
echo "Mul: \t$r3"  
echo "Div: \t$r4"
```

The usage of * in expr command does not directly support for multiplication. Because it gives different meanings. So the **backward slash with * symbol** provides the multiplication in the expr command.
II. EXAMPLE OF ARITHMETIC OPERATIONS USING C STYLE

SOURCE CODE

```bash
echo "--------------------------------------------------------------------------"

Arithmetic Operations using C-Style

Enter the number 1:
15
Enter the number 2:
3
Add: 18
Sub: 12
Mul: 45
Div: 5

The Syntax is $(e1, e2, ..en). Each expression e1, e2, ..en can be closed by ()
```

```bash
# performing arithmetic operations using expr command
r1=$((a+b))
r2=$((a-b))
r3=$((a*b))
r4=$((a/b))

# print the results
echo "Add: \$r1"
echo "Sub: \$r2"
echo "Mul: \$r3"
echo "Div: \$r4"
```
## RELATIONAL OPERATORS

### RELATIONAL OPERATORS FOR NUMBERS

<table>
<thead>
<tr>
<th>S.N</th>
<th>OPERATOR</th>

SOURCE CODE

```bash
echo "---------------------------------------------------"
echo "Files and Folders in Parent Directory"
echo "---------------------------------------------------"
for i in $(ls ..)
do
echo $i
done
```

OUTPUT

```
Path of Parent Directory: $ ls ..
```

IX. LISTING FILES AND FOLDERS IN CURRENT DIRECTORY

SOURCE CODE

```bash
echo "---------------------------------------------------"
echo "Files and Folders in Current Directory"
echo "---------------------------------------------------"
for i in $(ls)
do
echo $i
done
```

Path of Current Directory: $ ls
LIST FILES IN LONG FORMAT

- The command `ls -l` provides the detailed format of showing the files and folders in current file system.

  1. Content Permissions
  2. Number of links to the content
  3. Owner of the content
  4. Group owner of the content
  5. Size of the content (in bytes)
  6. Last modified date / time
  7. Name of the file / directory name
Long Listing of Files and Folders

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
</table>

```bash
> ls -l
total 52
-rw-r--r-- 1 runner runner  0 May 4 05:16 5
-rw-r--r-- 1 runner runner 483 May 4 03:04 arth1.sh
-rw-r--r-- 1 runner runner 454 May 4 03:16 arth2.sh
-rw-r--r-- 1 runner runner  0 May 4 05:15 b
-rw-r--r-- 1 runner runner  42 May 4 05:35 city.txt
-rw-r--r-- 1 runner runner 202 May 4 06:30 current.sh
-rw-r--r-- 1 runner runner  700 May 4 05:51 filect.sh

-rw-r--r-- 1 runner runner 201 May 4 06:18 test.sh
drwxr-xr-x 1 runner runner  26 May 4 05:41 tt
-rw-r--r-- 1 runner runner 13  May 4 05:40 wel.txt
```

**CONTENT PERMISSION**

- In content permission, the column 1 indicates the file type. They are:
  - `-` means for regular file
  - `d` means for directory
  - `b` means for special block file
  - `c` means for special character file
- In content permission, the next column indicates the file permissions such as read, write and execute:
  - Read → represents the read mode which is code value 4
  - Write → represents the write mode which is code value 2
  - Execute → represents the execute mode which is code value 1.
SHELL FUNCTION

- Shell program supports the function which is used to implement the variables as well as execute the linux commands.

Syntax1

```bash
function <name>
{
    # user code
}
```

Example

```bash
function show
{
    # user code
}
```

Syntax2

```bash
<function-name>()
{
    # user code
}
```

Example

```bash
show()
{
    # user code
}
```

CALLING FUNCTION

- Shell function can be called using its name only.
- The operation () should not be used while calling the function.
I. EXAMPLE OF SHELL FUNCTION

SOURCE CODE

echo "------------------------------------------"
echo "Shell Function"
echo "------------------------------------------"
disp() {
   echo "Good Morning ...
}
# calling function
disp

OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; sh fun1.sh</td>
<td><img src="image.png" alt="Shell Output" /></td>
</tr>
</tbody>
</table>

The operator symbol () is not allowed while calling the shell function.
SHELL FUNCTION WITH ARGUENTS

- Shell function supports the arguments
- The arguments are given after the function name while calling the function
- Each argument is separated by space
- The positional parameters like $1, $2, etc... will receive the values of function arguments inside the function definition

II. EXAMPLE OF SHELL FUNCTION WITH ARGUENTS

SOURCE CODE

echo "---------------------------------------------"
echo "Shell Function with Arguments"
echo "---------------------------------------------"

# creating a shell function
disp()
{
    a=$1
    b=$2
    rs=`expr $a + $b`
    echo "Sum is: $rs"
}

# calling function with arguments
disp 12 21

OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; sh fun2.sh</td>
<td>Q x</td>
</tr>
<tr>
<td></td>
<td>Shell Function with Arguments</td>
</tr>
<tr>
<td>Sum is: 33</td>
<td></td>
</tr>
</tbody>
</table>

SHELL FUNCTION WITH RETURN STATEMENTS

- Like c language, shell function returns the values
- The return keyword is used to return the values in the shell function
- The returned result of calling function can be obtained using the special symbol $? (by default, the return values of the function will be stored to the built-in variable $?)

NOTE

- It is an important to note that, the shell function will return a single value.

III. EXAMPLE OF SHELL FUNCTION WITH RETURN VALUE

SOURCE CODE

```bash
echo "-------------------------------------------------------------"
echo "Shell Function with Return Value"
echo "-------------------------------------------------------------"
a=12
b=23
rs=0
# shell function
disp()
{
    rs=`expr $a + $b`
    # return the variable
    return $rs
}
# calling function
disp
# get the return value from function using $?
k=$?
echo "Sum is: $k"
```

```bash
echo "$-"-------------------------------------------------------------"
echo "$t\tShell Function with Return Value"
echo "$-"-------------------------------------------------------------"
a=12
b=23
rs=0
# shell function
disp()
{
    rs=`expr $a + $b`
    # return the variable
    return $rs
}
# calling function
disp
# get the return value from function using $? 
k=??
echo "$Sum is: $k"
```
OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ah fun3.sh</code></td>
<td>Q x</td>
</tr>
</tbody>
</table>

Shell Function with Return Value

Sum is: 35

COMMAND SUBSTITUTION

- In shell, assigning the built-in command to a user defined variable is called as command substitution
- This is done using the special symbol `command-name` or $(command-name)

Syntax 1

Variable-Name=`command-name`

Example

files=`ls` # the output of ls command is stored to the variable called files.

dirpath="test"
files=`ls $dirpath` # the contents of test directory are stored to the variable called files

Syntax 2

Variable-Name=$(command-name)

Example

files=$(ls) # the output of ls command is stored to the variable called files.
I. EXAMPLE OF COMMAND SUBSTITUTION

SOURCE CODE

echo "-------------------------------------------"
echo "\tCommand Substitution"
echo "-------------------------------------------"

# date command Substitution
rs=`date`
# k=$(date)
# print the output of date command via variable
echo "Current Date: \n"$rs

OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sh cmdsub1.sh</code></td>
<td><img src="image" alt="Output" /></td>
</tr>
</tbody>
</table>

Current Date:
Fri Apr 30 02:40:07 UTC 2021

>}
II. COMMAND SUBSTITUTION-FILE COPYING BETWEEN DIRECTORIES

SOURCE CODE

```bash
# path of source directory
path="/home/runner/OS-Lab/d1"

# for loop
for i in $src
do
cp $i $tar
echo "$i is successfully copied to $tar/$i"
done
```

OUTPUT

```
[Output shown with file listing and copying process]
```

RESULT

Thus the operators and shell functions of the shell programming have been executed successfully.
EX.NO: 5 SHELL ARRAYS

AIM

To practice the arrays in shell programming.

SHELL ARRAY

- Array is a set of elements which are having same type or different type
- It is an example of linear data structures (sequential data structure)
- It is accessed by the index number which starts from 0 to n-1
- It supports the storage, retrieval, insertion, deletion and updation
- In shell, the array can be created with help of the special operator symbol () instead of square operator []
- Unlike other compiled languages c/c++/c#/java, the shell follows the dynamic data typed system. So no need to mention the data type in the creation of an array.

Syntax

```
User-defined-name = (Element 1 Element 2 ...Element n)
```

Where,

Element 1, Element 2, ...Element n can be Same Type or Different Type.

Example

```
arr=(12 34 59)           // homogenous collection
arr=("Sachi" 12.41 55 true)    // heterogeneous
```

Length

- Array length can be done by using the special symbol # followed by @ or * symbol along with array name
- It is very important to note that, the curly braces operators {} are used for accessing the array in shell

Syntax

```
{#<array-name>[@]}
```

(OR)

```
{#<array-name>[@]}
```
Example

```
ls=(12 34 55 99)
len=${#ls[@]}
(OR)
len=${#ls[*]}
```

Accessing Individual array contents
- The contents of the array can have accessed by using its index location

**Example**

```
ls[0] → 12
ls[1] → 32
```

Printing Individual Element
- The individual element of an array can be displayed using the curly braces `{}` along with array name

**Syntax**

```
$arrayname[index-number]
```

**Example**

```
echo ${ls[1]} // display the second element
echo ${ls[3]} // display the fourth element
```

Accessing Entire array contents
- The entire array elements can be called using the star symbol `*` or `@` with array name.
- It is an important to note that, if the index number is `*` or `@`, the whole elements of the array are referenced.

**Example**

```
${ls[*]} → contains the entire array elements
echo ${ls[*]} → show the array contents at the same time.
```
Commands to check the Shell Types

$ cat /etc/shells

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat /etc/shells</td>
<td>/bin/sh</td>
</tr>
<tr>
<td></td>
<td>/bin/bash</td>
</tr>
<tr>
<td></td>
<td>/bin/rbash</td>
</tr>
<tr>
<td></td>
<td>/bin/dash</td>
</tr>
</tbody>
</table>

I. EXAMPLE OF ARRAY CREATION FOR HOMOGENEOUS TYPE

(/home/runner/Latest-Shells-21/arr1.sh)

**SOURCE CODE**

```bash
echo "---------------------------------------------"
echo "Shell Array for Same Type of Elements"
echo "---------------------------------------------"

# Array Creation
lb=(12 45 77 99 88)

# print the contents of array at the same time
echo "Array Contents using name"
echo ${lb[*]}

# print the length of the array
echo "Length of the Array: ${#lb[@]}"
echo "Array Contents using for loop"
echo "---------------------------------------------"
```

OR

```
${ls[@]}  ➔ contains the entire array elements
echo ${ls[@]} ➔ show the array contents at the same time.
```
# print the contents of array
for i in ${lb[*]}
do
echo $i
done

OUTPUT

II. EXAMPLE OF ARRAY CREATION FOR HETEROGENEOUS TYPE

(/home/runner/Latest-Shells-21/arr2.sh)

SOURCE CODE

echo "----------------------------------------"
echo "Shell Array for Different Type of Elements"
echo "----------------------------------------"

# Array Creation
lb=("Shiva" 21 72.93 True)

# print the contents of array at the same time
echo "Array Contents using name"
echo ${lb[*]}

# print the length of the array

different type elements of array.

display the array contents at the same time using the name.
```bash
# Length of the Array:
for i in $lb[@]; do
  echo $i
done

Output:

Array Contents using name
Shiva 21 72.93 True
Length of the Array: 4
Array Contents using for loop
Shiva
21
72.93
True

III. INDEX BASED ARRAY CREATION FOR HETEROGENEOUS TYPE
(/home/runner/Latest-Shells-21/arr3.sh)

SOURCE CODE

# Empty array
ls=()
# store the elements to array using index number
ls[0]=12
```

```
# Empty array creation
```
ls[1]=21
ls[2]="M"
ls[3]=True
ls[4]="Rohit"

# print the contents of array at the same time
echo "Array Contents using name"
echo ${ls[*]}

# print the length of the array
echo "Length of the Array: ${#ls[@]}"
echo "Array Contents using for loop"
for i in ${ls[*]}
    do
    echo $i
    done

OUTPUT

<table>

Thus the arrays using shell programming have been executed successfully.
EX.NO: 6 PROCESS SYSTEM CALLS – FORK, EXIT, WAIT

AIM

To practice the system calls such as fork, wait, exit using linux c programming.

SYSTEM CALLS

- It is an interface between process and kernel
- It is way for programs to interact with OS
- Five different types of system calls are available. They are
  1. Process Control
  2. File Management
  3. Device Management
  4. Information Management
  5. Communication
1. Process Control
   - This system calls perform the task of process creation, process termination, etc.

Functions
   - End and Abort
   - Load and Execute
   - Create Process and Terminate Process
   - Wait and Signed Event
   - Allocate and free memory

2. File Management
   - It handles file manipulation jobs like creating a file, reading, and writing, etc.

Functions
   - Create a file
   - Delete file
   - Open and close file
   - Read, write, and reposition
   - Get and set file attributes

3. Device Management
   - It performs the job of device manipulation like reading from device buffers, writing into device buffers, etc.

Functions
   - Request and release device
   - Logically attach/ detach devices
   - Get and Set device attributes

4. Information Management
   - It handles information and its transfer between the OS and the user program.

Functions
   - Get or set time and date
5. Communication

- These types of system calls are specially used for interprocess communications.

Functions

- Create, delete communications connections
- Send, receive message
- Help OS to transfer status information
- Attach or detach remote devices

PROCESS CONTROL SYSTEM CALLS

- It deals with process creation, process termination, etc, …

Examples

<table>
<thead>
<tr>
<th>S.N</th>
<th>Linux</th>
<th>Windows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>fork()</td>
<td>CreateProcess()</td>
<td>Create a child process</td>
</tr>
<tr>
<td>2.</td>
<td>exit()</td>
<td>ExitProcess()</td>
<td>Terminate the process</td>
</tr>
<tr>
<td>3.</td>
<td>wait()</td>
<td>WaitForSignalObject()</td>
<td>Wait for the child process termination</td>
</tr>
</tbody>
</table>

fork()

- It is an important system calls which is used to create a new process in the OS
- The newly created process is called as child process and caller of the child process is called as parent process
- It takes no arguments and returns the process ID
- It is called once but returns twice (once in parent and once in the child)
- The new process gets a copy of the current program, but new process id (pid). The process id of the parent process (the process that called fork()) is registered as the new processes parent pid (ppid) to build a process tree.
• It is an important to note that, Unix / Linux will make an exact copy of the parent's address space and give it to the child. Therefore, the parent and child processes have separate address spaces.

• It returns the following values:
  - Negative → new process creation was unsuccessful
  - Zero → returned to child process
  - Positive → returned to parent (caller) process

**Child Process**

• The newly created process is called as child process

• It is identified by the return code is 0

**Parent Process**

• The caller of the newly created process is called as parent process

• It is identified by the return code is positive value

**Formula**

\[
\begin{align*}
\text{Total number of processes (T)} & : 2^n \\
\text{Total number of Child processes (C)} & : 2^n - 1 \\
\text{Total number of Child processes (P)} & : T - C
\end{align*}
\]

**NOTE**

• **After the fork(), both parent and child processes are running simultaneously**

• The newly created process is called as child process which is identified by the return code is 0 and the caller of the child process is called as parent process which is identified by positive value (>0)

• Program statements before fork() is common for both child and parent processes but after fork() call, the rest of the program instructions will be allocated separately for child and parent process

• Child and parent processes don’t share common address space. They are having own memory address space. So if there are any changes in child process won’t reflect the parent process. Similarly, if there are any changes in parent processes won’t reflect the child process.
WHICH PROCESS RUNS FIRST (b/w parent and child process)

- It an important to note that, there is no rule about which process runs first between parent and child processes.
- As soon as a process is ready for execution (i.e. the fork system call returns), it may run according to the scheduling configuration (priority, scheduler chosen, etc.).
- Depending on how the process is added to the scheduler, either process may be scheduled first after returning from fork.

REQUIRED HEADER FILES

1. #include<stdio.h>
   - This header file is used for printf(), scanf(), etc, …
2. #include<unistd.h>
   - This header file is used for fork(), getpid(), getppid(), etc, …
3. #include<sys/types.h>
   - This header file is used for pid_t, etc, …
4. #include<sys/wait.h>
   - This header file is used for wait(), etc, …
5. #include<stdlib.h>
   - This header file is used for exit(), etc, …

TOOLS SUPPORT

Compiler : gcc compiler (gcc <filename>.c)
Execution : ./a.out (assembly output)
OS : Linux OS platform
Terminal : Online linux terminal (www.replit.com)
I. EXAMPLE OF SINGLE FORK

(fork1.c)

SOURCE CODE

```c
#include<unistd.h>
#include<stdio.h>
int main()
{
    printf("-----------------------------------\n");
    printf("\tSimple Fork()\n");
    printf("------------------------\n");
    // calling fork()
    fork();
    printf("Hello World\n");
    return 0;
}
```

OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>gcc fork1.c</td>
<td></td>
</tr>
<tr>
<td>./a.out</td>
<td></td>
</tr>
</tbody>
</table>

```
Simple Fork()
Hello World
Hello World
```

Total Number of Processes are $\rightarrow 2^n$

$\rightarrow 2^1$

$\rightarrow 2$
- When the child process is created, both the parent process and the child process will point to the next instruction (same Program Counter) after the fork().

- In this way the remaining instructions or C statements will be executed the total number of process times, that is $2^n$ times, where $n$ is the number of fork() system calls.
II. CALLING DOUBLE FORK

SOURCE CODE

```c
#include <unistd.h>
#include <stdio.h>

int main()
{
    printf("------------------------------------------------
");
    printf("Calling Double Fork()\n");
    printf("------------------------------------------------
");
    // calling double fork()
    fork();
    fork();
    printf("Good Morning\n");
    return 0;
}
```

OUTPUT

```
gcc fork2.c
./a.out
Calling Double Fork()
Good Morning
Good Morning
Good Morning
Good Morning
```

Total Number of Processes are

- \(2^n\)
- \(2^2\)
- \(4\)
III. CALLING TRIPLE FORK

SOURCE CODE

```c
#include<unistd.h>
#include<stdio.h>

int main()
{
    printf("---------------------------------------------\n");
    printf("Calling Triple Fork()\n");
    printf("---------------------------------------------\n");
    // calling triple fork()
    fork();
    fork();
    fork();
    printf("Welcome to Chennai\n");
    return 0;
}
```

OUTPUT

```
> gcc fork3.c
> ./a.out

Calling Triple Fork()
Welcome to Chennai
Welcome to Chennai
Welcome to Chennai
Welcome to Chennai
Welcome to Chennai
Welcome to Chennai
Welcome to Chennai
```

Total Number of Processes are $2^n$, $2^3$, and 8.
IV. PRINT THE RETURNED VALUE OF CHILD AND PARENT PROCESSES USING FORK

SOURCE CODE

```c
#include<stdio.h>
#include<stdlib.h>
#include<sys/types.h>

int main()
{
    pid_t id;
    printf("----------------------------------------\n");
    printf("Return Code of Parent & Child\n");
    printf("----------------------------------------\n");
    // calling fork()
    id=fork();
    if(id==0)
    {
        printf("Child Process is calling ...\n");
        printf("Returned Value of Child Process : %d\n",id);
    }
    else
    {
        printf("Parent Process is calling ...\n");
        printf("Returned Value of Parent Process : %d\n",id);
    }
    return 0;
}
```

This header supports the `pid_t` type.

Child Process: It is identified by 0

Parent Process: It is identified by >0
Usage of getpid() and getppid()

- Two major functions which are used to get the process ids. They are
  1. getpid()
  2. getppid()

1. getpid()
- It is a built-in function and available in `<unistd.h>` header file
- It is used to return the process ID of child process (newly created process)
- Return value: `pid_t`

2. getppid()
- It is a built-in function and available in `<unistd.h>` header file
- It is used to return the process ID of parent process (caller of the newly created process)
- Return value: `pid_t`

`pid_t`
- It stands for process id type and built-in variable to store the process ids of parent and child function
- It is the type of the process ID which returns an unsigned integer value.
- It is available in `<sys/types.h>`
V. DISPLAY THE PROCESS ID (PID) OF PARENT AND CHILD PROCESSES USING GETPID() AND GETPPID()

SOURCE CODE

```c
#include<unistd.h>
#include<stdio.h>
#include <sys/types.h>

int main()
{
    int id;
    printf("-----------------------------------------
");
    printf("Process ID of Parent & Child
");
    printf("-----------------------------------------
");

    // calling fork()
    id=fork();
    if(id==0)
    {
        printf("Child Process is calling ...
");
        printf("Process ID (PID) of Child Process : %d",getpid());
    }
    else
    {
        printf("Parent Process is calling ...
");
        printf("Process ID (PID) of Parent Process : %d",getppid());
    }
    return 0;
}
```
Wait()

- It is system call and available in `#include<sys/wait.h>` file
- It blocks the current process (calling process), until one of its child processes terminate or a signal is received
- It takes one argument which is the address of an integer variable (stores the information of the process) and returns the process ID (PID) of completed child process
- Return type: `pid_t`
- If only one child process is terminated (finished its execution), then it returns the process ID of the terminated child process
- If more than one child processes are terminated, then it returns process ID of any terminated arbitrary child process.

The execution of `wait()` could have two possible situations.

1. If there are at least one child processes running when the call to `wait()` is made, the caller will be blocked until one of its child processes exits. At that moment, the caller resumes its execution.
2. If there is no child process running when the call to `wait()` is made, then this `wait()` has no effect at all. It returns -1 immediately.
NOTABLE POINTS

- `wait(NULL)` will block the parent process until any of its children has finished their execution (parent process will be blocked until child process returns an exit status to the operating system which is then returned to parent process)

- If child finishes before parent reaches `wait(NULL)` then it will read the exit status, release the process entry in the process table and continue execution until it finishes as well.

- Wait can be used to make the parent process wait for the child to terminate (finish) but not the other way around

- `Wait(NULL)` simply making the parent wait for the child.

- On success, `wait()` returns the process ID of terminated child process while on failure it returns -1

- Once child process finishes, parent resumes and prints the rest of the statements of parent process

exit()

- It is system call and available in `#include<stdlib>` file

- It takes only one parameter which is exit status as a parameter

- It is used to close all files, sockets, frees all memory and then terminates the process.

- The parameter 0 indicates that the termination is normal.
VI. EXAMPLE OF WAIT AND EXIT SYSTEM CALLS

SOURCE CODE

```c
#include<stdio.h>
#include<sys/types.h>
#include<unistd.h>
#include<stdlib.h>
#include<sys/wait.h>

int main()
{
    pid_t pd;
    printf("-----------------------------------------------\n");
    printf("wait() and exit()\n");
    printf("-----------------------------------------------\n");
    // execution of fork() call
    if (fork() == 0)
    {
        printf("Child is calling...\n");
        // normal termination
        exit(0);
    }
    else
    {
        // get the PID of terminated child process
        pd = wait(NULL);
        printf("Parent is calling...\n");
        // print the process IDs of parent and child processes
        printf("Parent PID\t: %d\n", getppid());
        printf("Child PID\t: %d\n", pd);
    }
    return 0;
}
```
VII. SUM OF NUMBERS IN ARRAY USING CHILD AND PARENT PROCESS

Task
Write a linux c program to find the sum of the numbers in array in child process and execute the parent process after the execution of child process using system calls.

Used System calls:

- fork()
- wait()

SOURCE CODE

```c
#include<stdio.h>
#include<stdlib.h>
#include<stdio.h>
#include<unistd.h>

int main()
{
    int i,a[]={1,5,7,8,9};
```
int s=0;
printf("---------------------------------------------------------------------------\n");
printf("Sum of Numbers in Child and Execution of Parent after the child\n");
printf("---------------------------------------------------------------------------\n");
// create new process by fork and return the value in p
int p=fork();
// if the returned value is negative value (unsuccessful status)
if(p<0)
{
    printf("Failed to create a new Process ...
");
    exit(0);
}
// if the returned value is equal to 0 (checking child process)
else if(p==0)
{
    printf("Child Process is calling...
");
    for(i=0;i<5;i++)
    {
        s=s+a[i];
    }
    printf("The result is: %d
",s);
    printf("Child Process is completed...
");
}
// if the returned value is positive (checking parent process)
else
{
    wait(NULL);
    printf("Parent Process is calling after the Child Process ...
");
}
return 0;
### OUTPUT

<table>
<thead>
<tr>
<th>Console</th>
<th>Shell</th>
</tr>
</thead>
<tbody>
<tr>
<td>gcc sumfork.c</td>
<td></td>
</tr>
<tr>
<td>./a.out</td>
<td></td>
</tr>
</tbody>
</table>

---

### RESULT

Thus the types of process system calls have been executed successfully.
EX.NO: 7 INTERPROCESS COMMUNICATION USING PIPE

AIM

To work with interprocess communication using pipe in Linux C programming.

IPC

- IPC stands for Inter Process Communication
- It is one of the mechanisms provided by the OS which allows processes to communicate with each other and synchronize their action
- Examples: Message Queue, Signals, Shared Memory, Pipes, etc,…

EXAMPLES TECHNIQUES OF IPC

- Shared Files
- Shared Memory
- Pipes (Named and Unnamed Pipes)
- Message Queues
- Sockets
- Signals

PIPES

- Pipe provides the communication between processes on the same computer or different computer or across the network
- It is classified as two types. They are
  1. Unnamed Pipe (PIPE)
  2. Named Pipe (FIFO)
Pipe Symbol

- The output of one command (read) can be given as the input of next command (write) that is called as pipe command. In linux terminal, it is indicated the symbol `|`

- **Two processes can be joined or communicated with help of the pipe symbol on the shell terminal**

![Diagram showing pipe symbol and processes](image)

- Both processes P1, P2 are executed simultaneously and P1 will pass data / message to Process P2 as it executes.

Example of Pipe Symbol in Linux Terminal

![Example of pipe symbol in Linux terminal](image)

- Here the output of `ls` command is given as an input to the `wc -l` command using pipe symbol (`|`).

- Hence, both `ls` command (Process P1) and `wc -l` command (Process P2) can be communicated through pipe symbol (`|`).

- Using pipe symbol, ‘n’ of processes or commands can be communicated.
I. IPC USING PIPE

PIPE SYSTEM CALL

- In linux c, the pipe system call is created by using the built-in function called `pipe()`

Example

```c
int pipe(int pd[2]);
```

- Here, pipe system call accepts only one argument, which is an integer array of two pipe descriptors.
- `pd[0]` is used for reading data / message from the pipe and `pd[1]` is used for writing data / message to the pipe.

Pipe (Unnamed Pipe or Anonymous Pipe)

- In linux, if the pipe has no name then it is called as unnamed pipe or anonymous pipe (gives communication between parent and child processes)
- It is a communication medium between two or more related or interrelated processes
- It is mainly used for interprocess communication. It has two ends. They are:
  1. First end is `fd[0]` which is used for reading mode
  2. Second end is `fd[1]` which is used for writing mode
- It is used for transferring data between two processes / commands / programs
- It acts like queue data structure. We can write 512 bytes at the same time but we can read ONLY ONE BYTE at the same time.
- It is an important to note that, pipe is an uni-directional (half duplex or one-way communication) that is either from left to right or right to left
- It is an important to note that, whatever is written on one end (Ex. write end) might visible on other end (Ex. read end)

Return Value of Pipe

- It returns 0 if successful otherwise it returns -1
- Return type: int
Required Header File

```
#include<unistd.h>
```

OPERATIONS OF PIPE

- One Way Communication between processes
  - One pipe system call is required
- Two Way Communication between processes
  - Two pipe system calls are required
  - By default, it is a half-duplex method. So the first process will communicate with second process or second process will communicate with first process. However, in order to achieve a full-duplex, another pipe is needed.

BUILT-IN METHODS OF PIPE

1. `write(pipe-descriptor[1], void * message, size_t count)`
   - This method is used to write the string message using the pipe end [1]
   - It takes three arguments such as descriptor, message and size
   - 1\textsuperscript{st} argument is pipe descriptor
   - 2\textsuperscript{nd} argument is message which is string type
   - 3\textsuperscript{rd} argument is count which is unsigned int type.
   - This method will return the number of bytes written on success case and will return -1 if the case is failure.
   - Return type: ssize_t

2. `read(pipe-descriptor[0], void * buffer, size_t count)`
   - This method is used to read the string message using the pipe end [0]
   - It takes three arguments such as descriptor, message and size
   - 1\textsuperscript{st} argument is pipe descriptor
   - 2\textsuperscript{nd} argument is message which is string type
• 3\textsuperscript{rd} argument is count which is \texttt{unsigned int} type.

• This method will return the number of bytes read on success case and will return -1 if the case is failure.

• Return type: \texttt{ssize_t}

3. close(pipe-descriptor)

• This method is used to close the pipe if pipe is already opened

• It takes only one argument which is the integer value of pipe descriptor

• It will return 0 on success case and -1 on failure case.

• Return type: \texttt{int}
I. SENDING AND RECEIVING STATIC MESSAGES BETWEEN TWO PROCESSES USING PIPE

(/home/runner/Latest-Shells-21/pipeex1.c)

SOURCE CODE

```c
#include <string.h>
#include <fcntl.h>
#include <unistd.h>
#include <stdio.h>
#include <stdlib.h>

int main()
{
    int r;
    // pipe descriptors
    int p[2];
    printf(" -------------------------------------------------------

tSending and Receiving Static Messages-Pipe
	n ---------------------------------------------

t

t
// Text Messages (fixed messages)
char *sms1="Good Morning"
char *sms2="Hello World"
unsigned int s=strlen(sms1);
char buf[1024];
// create unnamed pipe using pipe system call
r=pipe(p);
if(r<0)
{
    printf("Failed to created unnamed pipe...

exit(1);
}
// send messages to another process
write(p[1],sms1,strlen(sms1));
write(p[1],sms2,strlen(sms1));
printf("Two Messages are sent successully...(Process 1)
");
```
printf("---------------------------------------------------------
");
printf("Message from Unnamed Pipe: (Process 2)\n");

// read messages from the pipe (other end) using single buffer
read(p[0],buf,sizeof(buf));
printf("%s",buf);
    return 99;
}

OUTPUT

II. FINDING PRIME NUMBER USING PIPE
(Static Input)
(/home/runner/Latest-Shells-21/pipeex3.c)

SOURCE CODE

#include<fcntl.h>
#include <unistd.h>

        exit(1);
    }
    printf("Enter the number of messages to send: ");
    scanf("%d",&nl);
    printf("Enter the messages:\n");
    for(int i=0;i<nl;i++)
{ 
    printf("Message #%d: \n",i+1));
    scanf("%s",msg);
    // write message to process 2
    write(p[1],msg,50);
    // count the length of the message
    s+=strlen(msg);
    printf("\nOne SMS is sent\n");
    printf("\nSMS Length: %d\n",(int)strlen(msg));
    // increment the SMS count by the variable c with 1
    c++;
}
printf("%d Messages are Sent Successfully\n",c);
printf("Message from Unnamed Pipe:\n");
printf("Process 2:\n");
printf("---------------------------------------------\n");
for(int i=0;i<nl;i++)
{
    read(p[0],bf,50);
    printf("%s\n",bf);
}
return 99;
}
Sending & Receiving Dynamic Messages using Pipe

Enter the number of messages to send: 5
Enter the messages:
Message #1:
HelloWorld
    One SMS is sent
    SMS Length: 10
Message #2:
GoodMorning
    One SMS is sent
    SMS Length: 11
Message #3:
Welcome
    One SMS is sent
    SMS Length: 7
Message #4:
Super
    One SMS is sent
    SMS Length: 5
Message #5:
Nice
    One SMS is sent
    SMS Length: 4
5 Messages are Sent Successfully
Message from Unnamed Pipe:
Process 2:
HelloWorld
GoodMorning
Welcome
Super
Nice

V. PARENT AND CHILD PROCESS COMMUNICATION (IPC) USING PIPE

(/home/runner/Latest-Shells-21/ipcpipe.c)

Number of used Pipes : 1
Number of child processes : 1
Number of parent processes : 1
Major system calls used : pipe(), fork()
Types of Pipes : Unnamed Pipe()
Type of Communication : One way

SOURCE CODE

```
#include<fcntl.h>
#include <unistd.h>
#include<stdio.h>
#include<stdlib.h>
#include<sys/wait.h>

int main()
{
    int r;
    // pipe descriptors for read and write
    int p[2];
    printf("---------------------------------------------------------\n");
    printf("\tIPC-Parent and Child using Pipe (One Way)\n");
    printf("---------------------------------------------------------\n");
    // variables declarations
    char *sms=(char *)malloc(sizeof(char *));
    char buf[1024];
    // create unnamed pipe using pipe system call
    r=pipe(p);
    if(r<0)
    {
        printf("Failed to created unnamed pipe...\n");
        exit(1);
    }
    // call fork() to create parent and child processes
    int f=fork();
    if(f<0)
    {
        printf("Error in creating the processes...\n");
        exit(0);
    }
```
// child process
else if (f == 0)
{
    printf("Child Process (P1)\n");
    printf("Enter the message to send (50 characters maximum): ");
    fgets(sms, 50, stdin);
    // send message from child to parent using pipe
    write(p[1], sms, 50);
}
// parent process
else
{
    wait(NULL);
    printf("---------------------------------------------------------\n");
    printf("Parent Process (P2)\n");
    // receive message from child via pipe
    read(p[0], buf, 50);
    printf("Received Message:\n");
    printf("%s\n", buf);
}
return 99;

OUTPUT

```
> gcc ipcpipe.c
> ./a.out

IPC-Parent and Child using Pipe

Child Process (P1)
Enter the message to send (50 characters maximum): Hello Hi How are you?

Parent Process (P2)
Received Message:
Hello Hi How are you?
```

RESULT

Thus the interprocess communication using pipe has been executed successfully.
EX.NO: 8  INTERPROCESS COMMUNICATION USING NAMED PIPE

AIM

To work with interprocess communication using named pipe in linux c programming.

IPC USING NAMED PIPE (FIFO)

- FIFO stands for First in First Out
- A special kind of the file on the local storage that allows two or more number of processes to communicate with each other
- Named IPC object which provides communication between two unrelated processes
- Unlike pipe, it has name (identified by the unique name)
- Unlike pipe, it is a full duplex method which means that first process can communicate with second process and second process can communicate with first process.

DIFFERENCE BETWEEN PIPE AND FIFO

<table>
<thead>
<tr>
<th>S.N</th>
<th>FEATURES</th>
<th>PIPE (Unnamed Pipe)</th>
<th>FIFO (Named Pipe)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Description</td>
<td>It has no name (Unnamed IPC object)</td>
<td>It has a name (Named IPC object)</td>
</tr>
<tr>
<td>2.</td>
<td>Creation</td>
<td>It is created by the system call pipe()</td>
<td>It is created by the method mkfifo() or open()</td>
</tr>
<tr>
<td>3.</td>
<td>Existence</td>
<td>It does not exist in the file systems</td>
<td>It exists in the file system</td>
</tr>
<tr>
<td>4.</td>
<td>Nature</td>
<td>By default, it is an unidirectional</td>
<td>It is bidirectional, same FIFO can be used for reading and writing at the same time</td>
</tr>
<tr>
<td>5.</td>
<td>Read &amp; Write</td>
<td>Here reader and writer operations are done at the same time</td>
<td>Here, it does not require that both read and write operations to happen at the same time.</td>
</tr>
</tbody>
</table>
6. Processes

Here data transfer takes place between parent and child process.

It has multiple processes communicating through it, like multiple client server application.

7. Communication

Here communication is among the process having related process

In FIFO, it is not necessary for the process having the related process (unrelated process).

8. Support

Pipe is local to the system and can’t be used for the communication across the network

It is capable of communicating across different computers and network.

NOTE

- Neither pipes nor FIFO allow file positioning. Both reading and writing operations happen sequentially that is reading from the beginning of the file and writing at the end of the file.

Required Header File

```c
#include<sys/stat.h>   // used for creating FIFO i.e. mkfifo()
```

CAPACITY OF FIFO

- It has multiple readers or multiple writers

- Bytes from each writer are written automatically up to a maximum size of PIPE_BUF (4KB on Linux OS)
BUILT-IN METHODS OF NAMED PIPE (FIFO)

1. mkfifo(const char *pathname, mode_t mode)
   - It is used to create a FIFO file
   - It takes two arguments. They are
     - First argument is pathname of the newly created FIFO file which is string type (identified by char *)
     - Second argument is mode of the FIFO’s permissions.
   - Return type: int

2. open(fpath, mode, permission)
   - It is used to create a named pipe (FIFO)
   - It takes two arguments. First argument is file name and second argument is mode. The mode can be
     - O_CREAT (create mode)
     - O_WRONLY (write mode only)
     - O_RDONLY (read mode only)
     - O_RDWR (read and write support)
   - Return type: int

3. write(int file descriptor, void * message, size_t size)
   - It is used to write / send the data from one end to another end
   - It takes three arguments. They are
     1. First argument is the file object
     2. Second argument is data / message
     3. Third argument is the size of the data
   - Return type: ssize_t

4. read(int file descriptor, void * message, size_t size)
   - It is used to read / receive the data from named pipe
   - It takes three arguments. They are
     1. First argument is the file object
     2. Second argument is data / message
     3. Third argument is the size of the data
5. close(file descriptor)

- It is used to close the file descriptor if it is already opened
- It takes only one argument which is the file descriptor
- Return type: int

### I. EXAMPLE OF IPC USING FIFO (NAMED PIPE)
(/home/runner/Latest-Shells-21/fifo1.c)

---

**IPC using FIFO (Named Pipe)**

Three Messages are successfully sent to named pipe...

**Messages from FIFO:**

- Hello World.
- Good Morning.
- Welcome to Chennai.

---

RESULT

Thus the interprocess communication using named pipe has been executed successfully.
EX.NO: 9  MULTITHREADING USING PYTHON

AIM
To practice the multithreading programming using python language.

THREADING
- Thread is a path of the execution within a process.

TASK BASED TYPES
1. Single Threading
2. Multithreading

DIFFERENCE BETWEEN SINGLE THREAD AND MULTIPLE THREADS

<table>
<thead>
<tr>
<th>S.N</th>
<th>SINGLE THREAD</th>
<th>MULTITHREADING</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Performs single task</td>
<td>Performs multitasking. Doing more than one job at the same time</td>
</tr>
<tr>
<td>2.</td>
<td>It consists of only one thread</td>
<td>It consists of several threads</td>
</tr>
<tr>
<td>3.</td>
<td>It is used for experimental purpose</td>
<td>It is used for larger tasks</td>
</tr>
</tbody>
</table>

LIFE CYCLE OF THREADS
- Thread has five life cycles. It is always live in any of the state.
  1. New born state (New state)
  2. Runnable state
  3. Running state (execution state)
  4. Blocked state
  5. Dead state (End state)

BUILT-IN METHODS
1. start()
   - This is runnable state (waiting for the execution)
   - This is method is used to start the thread
• Return type: nothing

2. threading.currentThread().getName()

• This method is used to display the name of currently executing or running thread
• Return type: String

Thread Creation

• Thread is created by using the super class Thread

Thread(name=<user-defined-name, target=<function-name>, )

• It is a built-in class which is used to create a new thread object
• It takes two or more arguments
• First argument is name of thread. It can be any name set by the user. It is optional argument
• Second argument is target which is used to call the user defined function

Required Module

threading
I. EXAMPLE OF SINGLE THREAD

Tools used : VSC Editor
Platform OS : Windows 10
Language : Python 3

SOURCE CODE

```python
from threading import *

# user defined function
def welcome():
    print("Hello World...")
print("------------------------------------------")
print("Single Thread")
print("------------------------------------------")

# creating object for single thread
t1=Thread(target=welcome, name="Thread 1")

# start the thread by calling start method
t1.start()
```

OUTPUT

![Image of output showing the execution of the thread with "Hello World..." and "Single Thread" messages]
MULTITHREADING

- Process of executing more than one thread at the same time (Execution of multiple threads simultaneously)
- It is an important to note that, we can't predict which thread will run first.
- By all the threads will be running in parallel at the same time.
- It is an important to note that, the main or current thread can randomly start any thread from the list of threads.

II. EXAMPLE OF MULTITHREADING
(Asynchronous Processes)

Tools used : VSC Editor
Platform OS : Windows 10
Language : Python 3

SOURCE CODE
from threading import *

# user defined function 1
def m1():
    for i in range(3):
        print("Good Morning...")

# user defined function 2
def m2():
for i in range(3):
    print("Good Evening...")

# user defined function 3
def m3():
    for i in range(3):
        print("Good Night...")
print("------------------------------------------")
print("tMultithreading")
print("------------------------------------------")

# creating objects for multiple threads
T1=Thread(target=m1,name="Morning")
T2=Thread(target=m2,name="Evening")
T3=Thread(target=m3,name="Night")

# start the threads by calling start method
T1.start()
T2.start()
T3.start()

III. EXAMPLE OF MULTITHREADING
(Synchronous Processes using join() method)

Tools used : VSC Editor
Platform OS : Windows 10
Language : Python 3

Existing Issues

- By default, the threads are running parallel in multithreading
- In the execution of multithreading using asynchronous methods, the threads will be running in parallel. That’s why the output came differently in the previous example.
- So in order to execute thread one by one (sequential order) during the multithreading, the join method will be used.

SOURCE CODE

from threading import *

# user defined function 1
def m1():
    for i in range(3):
        print("Good Morning...")

# user defined function 2
def m2():
    for i in range(3):
        print("Good Evening...")

# user defined function 3
def m3():
    for i in range(3):
        print("Good Night...")

print("------------------------------------------")
print("Multithreading")
print("------------------------------------------")
# creating objects for multiple threads

```python
t1=Thread(target=m1,name="Morning")
t2=Thread(target=m2,name="Evening")
t3=Thread(target=m3,name="Night")

# start thread 1
t1.start()

# wait until thread 1 is finished (main and sub threads t2, t3 should wait)
t1.join()

# start thread 2 after thread 1
t2.start()

# wait until thread 2 is finished (main and sub threads t1, t3 should wait)
t2.join()

# start thread 3 after thread 2
t3.start()

# wait until thread 3 is finished (main and sub threads t1, t2 should wait)
t3.join()

# end of the main thread

thread3=Thread(target=m3,name="Night")
# start threads
t1.start()
t2.start()
t3.start()

# end of the main thread
print("End of the main thread...")

OUTPUT

GENERAL TYPES OF THREAD

- Like java, python supports two types of threads. They are
  1. Daemon thread
  2. Non daemon thread (User Thread)

1. Daemon Thread

- If a thread is running in background mode, then it is called as daemon thread
- It has low priority level than user thread
- This is created by adding the boolean value to the daemon argument of the Thread class.
2. Non Daemon Thread

- If a thread is running in **foreground mode**, then it is called as non daemon thread (user thread)
- It has high priority level than daemon thread
- This is created by the thread class.

**DIFFERENCE BETWEEN DAEMON THREAD AND NON DAEMON THREAD**

<table>
<thead>
<tr>
<th>S.N</th>
<th>DAEMON THREAD</th>
<th>NON DAEMON THREAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>It is always runs in background mode</td>
<td>It is always runs in foreground mode</td>
</tr>
<tr>
<td>2.</td>
<td>Main program does not wait for daemon thread to finish its task</td>
<td>Here main program waits for user threads have to terminate</td>
</tr>
<tr>
<td>3.</td>
<td>It has low priority</td>
<td>It has high priority</td>
</tr>
<tr>
<td>4.</td>
<td>It is not used for important task. It is generally used for some background tasks which are not important</td>
<td>Any important task is done by the user thread.</td>
</tr>
<tr>
<td>5.</td>
<td>It is created by the Python Virtual Machine (PVM)</td>
<td>It is created by the application or program.</td>
</tr>
<tr>
<td>6.</td>
<td>If all the threads are finished their execution, the PVM will force the daemon threads to finish their execution.</td>
<td>PVM won't force the user threads for termination. So it waits for user threads to terminate themselves.</td>
</tr>
</tbody>
</table>

from threading import *
from time import sleep

# user defined function 1
def m1():
    for i in range(3):
        print("Good Morning...")
sleep(2)

# user defined function 2
def m2():
    for i in range(3):
        print("Good Evening...")

# user defined function 3
def m3():
    for i in range(3):
        print("Good Night...")

print("------------------------------------------------------------------")
print(">Daemon Thread")
print("------------------------------------------------------------------")

# creating objects for multiple threads
# convert thread t1 to daemon thread by setting the boolean true to the
daemon argument of thread class

Convert user thread to non-daemon thread.

t1=Thread(target=m1,name="Morning", daemon=True)
# non daemon threads

t2=Thread(target=m2,name="Evening")
t3=Thread(target=m3,name="Night")
# start the thread by calling start method

t1.start()
t2.start()
t3.start()

OUTPUT

```
C:\Users\Krishna\Documents\Ganesh VS\Lab21>py ethreadS.py

Daemon Thread

Good Morning...
Good Evening...
Good Evening...
Good Night...
Good Evening...
Good Night...
Good Night...

C:\Users\Krishna\Documents\Ganesh VS\Lab21>
```

NOTE

- In the above output screenshot, the daemon thread t1 → Good Morning is still running in the background mode.
- Even though all threads (including main thread) are terminated, the daemon thread is still alive and running in the background.
II. EXAMPLE OF NON DAEMON THREAD

Tools used : VSC Editor
Platform OS : Windows 10
Language : Python 3

SOURCE CODE

```python
from threading import *
from time import sleep

# user defined function 1
def m1():
    for i in range(3):
        print("Good Morning...")
        sleep(2)

# user defined function 2
def m2():
    for i in range(3):
        print("Good Evening...")

# user defined function 3
def m3():
    for i in range(3):
        print("Good Night...")

print("----------------------------------------------------------")
print("\tNon Daemon Thread(User Threads)")
print("----------------------------------------------------------")

# creating objects for multiple threads
# Non Daemon Threads
t1=Thread(target=m1,name="Morning")
t2=Thread(target=m2,name="Evening")
t3=Thread(target=m3,name="Night")
# start the threads by calling start method
t1.start()
```
t2.start()
t3.start()

OUTPUT

In the previous example, main thread and user threads are terminated. But still daemon thread t1 → Good Morning is running in background jobs.

Here, main thread and user threads are terminated. No threads are running in background.

RESULT

Thus the multithreading programming using python has been executed successfully.
EX.NO: 10  FILE ALLOCATION STRATEGIES

AIM

To practice the file allocation strategy in linux programming.

FILE ALLOCATION METHODS

- It defines, how the files are stored in the disk blocks.
- It supports three methods. They are
  1. Sequential File Allocation (Contiguous Allocation)
  2. Indexed File Allocation
  3. Linked File Allocation

BENEFITS

- Efficient disk space utilization
- Fast access to the file blocks

1. SEQUENTIAL FILE ALLOCATION (CONTIGUOUS ALLOCATION)

- Process of allocating resources to the contiguous blocks are called as sequential file allocation
- Both sequential and direct accesses are supported by this method.
- The directory entry for a file with contiguous allocation contains
  - Address of starting block
  - Length of the allocated portion.
Example 1

```
  count
  0 1 2 3
  4 5 6 7
  8 9 10 11
  12 13 14 15
  16 17 18 19
  20 21 22 23
  24 25 26 27
  28 29 30 31
```

Directory

<table>
<thead>
<tr>
<th>file</th>
<th>start</th>
<th>length</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>tr</td>
<td>14</td>
<td>3</td>
</tr>
<tr>
<td>mail</td>
<td>19</td>
<td>6</td>
</tr>
<tr>
<td>list</td>
<td>28</td>
<td>4</td>
</tr>
<tr>
<td>f</td>
<td>6</td>
<td>2</td>
</tr>
</tbody>
</table>

Example 2

```
  Blocks
  0 1 2 3
  4 5 6 7
  8 9 10 11
```

**Hard Disk**

**Directory**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Start</th>
<th>Length</th>
<th>Allocated Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc.text</td>
<td>0</td>
<td>3</td>
<td>0,1,2</td>
</tr>
<tr>
<td>video.mp4</td>
<td>4</td>
<td>2</td>
<td>4,5</td>
</tr>
<tr>
<td>jtp.docx</td>
<td>9</td>
<td>3</td>
<td>9,10,11</td>
</tr>
</tbody>
</table>

Contiguous Allocation
I. EXAMPLE OF SEQUENTIAL ALLOCATION METHOD

SOURCE CODE

```c
#include<stdio.h>
#include<string.h>
#include<stdlib.h>
#define BLOCKSIZE 50
int b[BLOCKSIZE+1];
int number,length;
void seq_fileallocation()
{
    printf("Enter the block number: ");
    scanf("%d",&number);
    // check for invalid number
    if(number>BLOCKSIZE)
    {
        printf("Invalid Block Number.\nPLease Enter the block number in the
range between 1 to 50\n");
    }
    else
    {
        // check the slot is free or not
        if(b[number]==0)
        {
            printf("Enter the number of lengths for the block %d: ", number);
            scanf("%d",&length);
            int c=0;
            // increment the counter for the blocks which are given by the user
            for(int i=number;i<number+length;i++)
            {
                if(b[i]==0)
                {
```

c++;  
    }
}

// if counter equals to exact length, then slot should be free
if (c==length)
{
    // allocate file / block for the user request
    for (int i=number;i<number+length;i++)
    {
        b[i]=1;
        printf("block %d is allocated ...\n",i);
    }
    printf("File is allocated successfully for the block %d\n",number);
}
else if((number+length)>BLOCKSIZE)
{
    printf("File lengths are too out of range than MAX Capacity of Block %d...\n",BLOCKSIZE);
}
else
{
    printf("File lengths are not free for the given block\n");
}
else
{
    printf("File / Block is already Allocated\nPlease try some block %d\n",number);
}

// print the contents of table
void disp()
{
    for(int i=1;i<BLOCKSIZE+1;i++)
    {
        printf(" %d",b[i]);
        if(i%8==0)
            printf("\n");
    }
    printf("\n");
}

int main()
{
    // allot the inputs for the blocks
    for(int i=1;i<BLOCKSIZE+1;i++)
    {
        b[i]=0;
    }

2. INDEXED AL FILE ALLOCATION

- Unlike sequential file allocation, this method uses an additional block called as the **index block** which is used to store all the disk pointers.

- For each file, there is an individual index block.

- In the index block, the ith entry holds the disk address of the ith file block.

- It is important to note that, **indexed block does not hold the file data**, but **it holds the pointers to all the disk blocks allotted to the particular file**.

- The directory entry contains the address of the index block as shown in the below image:

**PICTORIAL REPRESENTATION**

![Diagram of Indexed File Allocation](image)

**Directory Entry**

<table>
<thead>
<tr>
<th>File</th>
<th>Index Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>bus</td>
<td>11</td>
</tr>
</tbody>
</table>

The diagram illustrates how the directory entry points to the index block, which in turn points to the file blocks.
II. EXAMPLE OF INDEXED ALLOCATION METHOD

SOURCE CODE

```c
#include<stdio.h>
#include<string.h>
#include<stdlib.h>
#define BLOCKSIZE 50
int b[BLOCKSIZE+1], ib[BLOCKSIZE+1];
int number,length;
void indexed_allocation()
{
    printf("Enter the index block number: ");
    scanf("%d", &number);
    // check for invalid number
    if(number>BLOCKSIZE)
    {
        printf("Invalid index Block Number. Please Enter the index block number in the range between 1 to 50\n");
    }
    else
    {
        // check the slot is free or not
        if(b[number]==0)
        {
            printf("Enter the number of files for the block %d: ", number);
            scanf("%d", &length);
            printf("Enter the blocks:\n");
            for(int i=0; i<length; i++)
            {
                printf("Files #\%d: ",(i+1));
                scanf("%d", &ib[i]);
            }
        }
    }
}
```
int c=0;
// increment the counter for the blocks which are given by the user
for(int i=0;i<length;i++)
{
    if(b[ib[i]]>BLOCKSIZE)
    {
        printf("Index Block is Out of Range.\nP lease enter the blocks in the range between 1-50\n");
        break;
    }
    else if(b[ib[i]]==0)
    {
        c++;
    }
}
// if counter equals to exact length, then slot should be free
if(c==length)
{
    // allocate file / block for the user request
    for(int i=0;i<length;i++)
    {
        b[ib[i]]=1;
        printf("Index block %d is allocated ...\n",ib[i]);
    }
    printf("File is allocated successfully for the block %d\n",number);
}
// if the submitted index block is greater than MAXIMUM give message
else
{
    printf("File lengths are not free for the given block\n");
}
else
{
    printf("File / Block is already Allocated\nPlease try some block");
}
}

// print the contents of table
void disp()
{
    for(int i=1;i<BLOCKSIZE+1;i++)
    {
        printf(" %d",b[i]);
        if(i%8==0)
        {
            printf("\n");
        }
    }
    printf("\n");
}

int main()
{
    // allot the inputs for the blocks
    for(int i=1;i<BLOCKSIZE+1;i++)
    {
        b[i]=0;
    }
    printf("Initial Block Table\n");

CHECKING ALREADY ALLOCATED INDEX NUMBERS 14, 25

RESULT

Thus the file allocation strategies like sequential and indexed file allocation methods have been executed successfully.
